

HEIDELBERG UNIVERSITY HOSPITAL

Do we need therapeutic drug monitoring for beta lactams or can we just use prolonged infusions?

Dr. Ute Blassmann, Pharm D Pharmacy Department Heidelberg University Hospital, Germany

Conflict of interest

There are no conflicts of interest to declare.

Contents

- Characteristics of beta lactams
- Toxicity of beta lactams
- Options for dose optimization
- Data supporting prolonged infusions of beta lactams
- Data on TDM-guided therapy

Characteristics of beta lactams

- 56 % of the antibiotics in ICU
- Mostly short half life (0.5 1 h)
 - Few exceptions e.g. ceftriaxone (9 h)
- Hydrophilic, predominant renal clearance, low volume of distribution, low intracellular penetration

```
High
— pharmacokinetic
variability
```

- In empiric therapy with unknown pathogen we need high concentrations at the site of infection to ensure maximal efficacy
- Higher than normal doses recommended for these patients from many experts

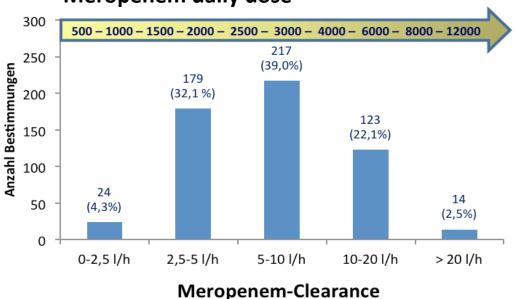

How would you dose meropenem?

- 34 year old man, post-operative meningitis, empiric therapy with meropenem in combination with vancomycin 190 cm, 98 kg, Crea 0.6 mg/dl
- 85 year old woman, recurrent urinary tract infection with ESBL E.coli (meropenem susceptible, MIC 2 mg/l), hospitalization due to urinary tract infection and extensive fluid loss

Meropenem clearance in 238 intensive care patients (557 samples) Frey O. Heidenheim General Hospital, Germany, unpublished data

Meropenem daily dose

Beta lactams are barely toxic...

- Anemia, thrombocytopenia, neutropenia
- Bleeding events, sometimes with abnormal coagulation parameters
- GIT problems, nausea, diarrhea
- Cholestatic jaundice, hepatitic failure
- Skin reactions
- Candida, Stenotrophomonas, Clostridium difficile
- Somnolence, dizziness, delirium, seizure

When was the last time you reported an adverse event from a beta lactam?

Neurotoxicity of beta lactams

- Well-known for penicillin G, imipenem/cilastin
- mechanism not fully understood, but is thought to interfere or inhibit of GABA binding to GABA_A
- seizure activity of these agents has been linked to the β-lactam ring as it shares a structural similarity with the GABA neurotransmitter
- Antibiotic concentrations in brain tissue, rather than the concentrations in cerebrospinal fluid are responsible

Elevated β-lactam concentrations associated with neurological deterioration in ICU septic patients M. BEUMIER ¹, G. S. CASU ¹, M. HITES ², F. WOLFF ³, F. COTTON ³, J.-L. VINCENT ¹, F. JACOBS ², F. S. TACCONE ¹

¹Department of Intensive Care, Erasme Hospital, Université Libre de Bruxelles (ULB), Brussels, Belgium; ²Department of Infectious Diseases, Erasme Hospital, Université Libre de Bruxelles (ULB), Brussels, Belgium; ³Department of Clinical Biochemistry, Erasme Hospital, Université Libre de Bruxelles (ULB), Brussels, Belgium

- 199 ICU septic patients with meropenem, piperacillin/tazobactam or cefepime
- 35 % (32-39%) worsening neurological status, no differences between antibiotics
- Increased c_{min}/MIC associated with worse neurology for meropenem (p<0.01) and piperacillin (p< 0.05)

Too much of a good thing: a retrospective study of β-lactam concentration-toxicity relationships

- 378 patients (73% ICU) with meropenem, piperacillin or flucloxacillin
- Neurotoxicity significant related to higher c_{min} (50% risk for developing neurotoxicity piperacillin c_{min}>361.4 mg/L, meropenem c_{min}>64.2 mg/L, flucloxacillin c_{min}>125.1 mg/L)
- Nephrotoxicity significant related to higher c_{min} (50 % risk for developing piperacillin c_{min}>452.65 mg/L, meropenem c_{min}>44.45 mg/L)
- Hepatotoxicity and C. difficile infections not related to c_{min}

- Home / Drugs / Drug Safety and Availability / FDA Drug Safety Communication: Cefepime and risk of seizure in patients not receiving dosage adjustments for kidney impairment

FDA Drug Safety Communication: Cefepime and risk of seizure in patients not receiving dosage adjustments for kidney impairment

Cases of <u>nonconvulsive status epilepticus associated with cefepime</u> are documented in the medical literature and have been identified in FDA's Adverse Event Reporting System (AERS) database . Most cases occurred in patients with renal impairment who did not receive appropriate dosage adjustment; however, <u>some cases occurred in</u> <u>patients receiving dosage adjustment appropriate for their</u> degree of renal impairment. In the majority of cases, the seizures were reversible and resolved after discontinuing cefepime and/or after hemodialysis.

=

Heidelberg University Hospital | EAHP Academy Brussels 2019 | Dr. Ute Blassmann

Neurotoxicity of cefepim

Systematic review with 37 studies, 48 % of patients were overdosed with FDA-approved dosing-guidance, 26 % experienced neurological symptoms

Timeline of clinical course:

Elevated CNS concentrations impaired CL, inflammation imposed by acute illness or disrupt BBB integrity Onset of neurotoxic effects altered mental status, may progess to myoclonus/seizures without intervention

Clinical improvement

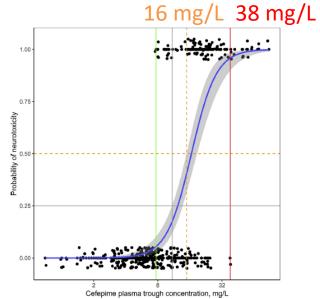

2 days after drug discontinuation, emergent hemodialysis by one day

Neurotoxicity of cefepim

Boschung-Pasquier et al. Cefepime neurotoxicity: tresholds and risk factors: A retrospective cohort study. Clin Microbio Infect 2019

- 319 patients
- Incidence of neurotoxicity 23%
- Associated with poorer renal function, longer duration, higher c_{min}
- c_{min}>16 mg/l 50% probability, c_{min}>38 mg/L always led to neurological side effects
- advise targeting c_{min} <7.5 mg/L to avoid the risk of neurotoxicity

Clinical Infectious Diseases

Lee et al. Continuous infusion versus intermittent bolus of beta-lactams* in critically ill patients with respiratory infections: A systematic review and meta-analysis 2018

Clinical Cure

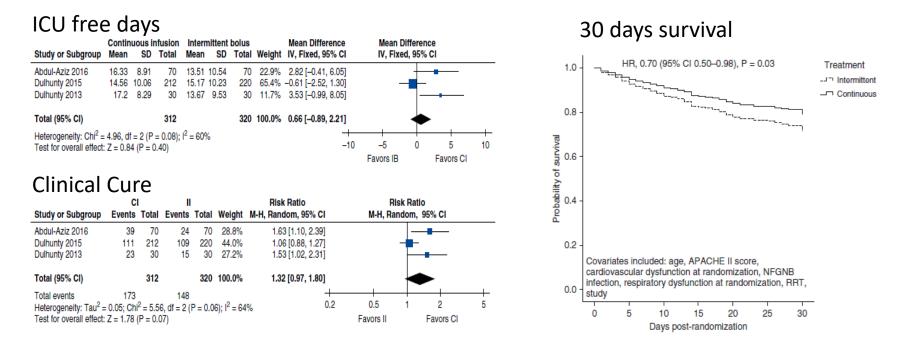

Coninuous infusion may be most beneficial in severely ill patients with more resistant gram-negative bacterial (subgroups: septic, high mortality rate)

*Ceftazidim, Imipenem, Ceftriaxon, Meropenem, Piperacillin, Cefepim, Temocilin, ticarcillin

Roberts et al. Continuous versus intermittent ß-lactam* infusion in severe sepsis: A metaanalysis of individual patient data from randomized trials 2016

*Piperacillin-tazobactam, meropenem, cefepime, ticarcillin-claculanate

Heidelberg University Hospital | EAHP Academy Brussels 2019 | Dr. Ute Blassmann

Optimization of the treatment with betalactam antibiotics in critically ill - Guidelines from the french society of pharmacology and therapeutics and of anaestheasia and intensive care medicine 2019

Suggest prolonged or continuous infusions to improve clinical cure rate in critically ill patients

- With septic shock/a high severity score
- Suffering from lower respiratory tract infections
- Suffering from infections due to bacteria with high MICs
- Suffering from infections due to non-fermenting gram-negative bacilli

Contents

- Characteristics of betalactams
- Toxicity of beta lactams
- Options for dose optimization
- Data supporting prolonged infusions of beta lactams
- Data on TDM-guided therapy

TDM-guided clinical outcome data

- Few studies (Wong G J Antimicrob Chemother 2018, DeWaele JJ et al Intensive Care Med 2014, Fournier A Burns 2018, Machado AS Clin Ther 2017)
- PK-PD target attainment was higher when using TDM
- No impact on clinical outcome

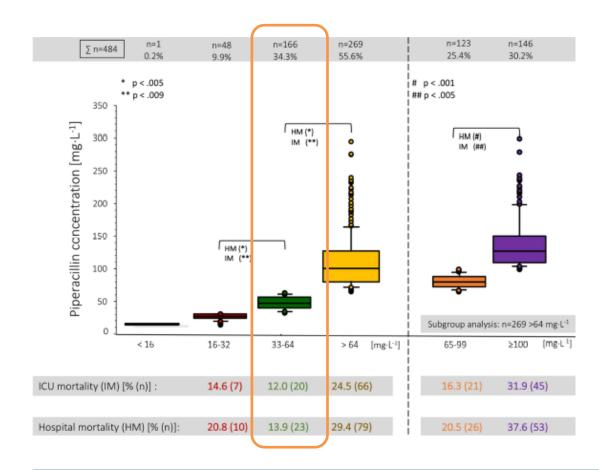

Richter DC et al. Therapeutic drug monitoring-guided continuous infusion of pipercillin/tazobactam signifcantly improves pharmacokinetic target attainment in critically ill patients: a retrospective analysis of four years of clinical experience. Infection 2019 (in press)

				\frown		Subgroup >64 mg·L ^{·1}		
PIP SC [mg·L ⁻¹]		<16	16-32	33-64	>64	65-99	≥100	
24 hours, % (N)	n=484	0.2 (1)	9.9 (48)	34.3 (166)	55.6 (269)	25.4 (123)	30.2 (146)	
TDM-guided, % (N)	n=449	1.1 (5)	14.7 (66)	62.4 (280)	21.8 (98)	17.4 (78)	4.5 (20)	

- 484 patients (933 samples), target 33-64 mg/L
- Improved PK target attainment from 34 to 62 %
- Reduced number of overdosed patients (>100 mg/L) from 30 to 5%

BMI, high CrCL, Age are risk factors

Patient with target attainment within the first 24 h showed lowest ICU mortality (p<0.009) and hospital mortality rate (p<0.005)

Heidelberg University Hospital | EAHP Academy Brussels 2019 | Dr. Ute Blassmann

STUDY PROTOCOL

Open Access

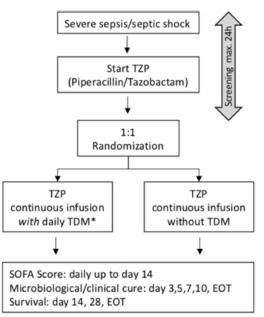

Therapeutic drug monitoring-based dose optimisation of piperacillin/tazobactam to improve outcome in patients with sepsis (TARGET): a prospective, multi-centre, randomised controlled trial

Stefan Hagel^{1,2*}, Sandra Fiedler³, Andreas Hohn⁴, Alexander Brinkmann⁵, Otto R. Frey⁶, Heike Hoyer⁷, Peter Schlattmann⁷, Michael Kiehntopf^{2,8,9}, Jason A. Roberts^{10,11}, Mathias W. Pletz¹ and on behalf of the TARGET Study Group

TARGET study protocol

^{*} up to day 10 / EOT: end of therapy

- Target 100% *f*T>4 MIC
- Outcome: change in SOFA Score (mortality, clinical cure, microbiological cure, overall antibiotic use e.g. duration, cumulative dosage, neurological outcome and toxicity (e.g. delirium), costeffectivness)
- Ongoing, recruting until late 2019

Conclusion

- Prolonged infusions are superior (without TDM)
- Neurotoxicity, Nephrotoxicity, resistance in the gut are described
- Benzylpenicillin, cefepime, piperacillin, carbapenems are considered to be the high-risk beta-lactams for neurotoxicity
 - Predisposing factors: renal impairment, excess concentrations, age, prior history of neurological disorders
- Dosing normograms and dosing software can help to individualise empirical dose to increase the chance of reaching PK-PD targets early
- TDM is the next reasonable step for continuous infusion to maximise the probability of target attainment and to minimise toxicity
